## 1 Group best-subset selection

### 1.1 MinT reconciliation

The unique solution of MinT is  $G = (S'W_h^{-1}S)^{-1}S'W_h^{-1}$ , which has a similar representation to a GLS estimator of a least square problem.

Consider a hierarchy consisting of  $n$  time series in total and  $n_b$  time series in the bottom level. Let  $y_t \in \mathbb{R}^n$  denote a vector of observations at time  $t$  of all time series in the hierarchy,  $b_t \in \mathbb{R}^{n_b}$  ( $n_b < n$ ) denote a vector of observations at time  $t$  of only the most disaggregated bottom-level series.

Therefore, the trace minimization problem can be reformulated in terms of a Quadratic Programming (QP) problem as follows:

$$\begin{aligned} \min_{G\hat{y}_h} \quad & (\hat{y}_h - SG\hat{y}_h)' W_h^{-1} (\hat{y}_h - SG\hat{y}_h) \\ \text{s.t.} \quad & GS = I_{n_b}. \end{aligned} \tag{1}$$

Note that the variable of interest is  $G\hat{y}_h$  rather than  $G$ . So we can get a unique solution of reconciled forecasts at the bottom level, while infinitely many least-squares solutions of  $G$  as the columns of  $\hat{y}_h' \otimes S$  are not linearly independent.

### 1.2 Best-subset selection

To eliminate the negative effect of some underperforming base forecasts on the performance of the reconciled forecasts, we want to **zero out some columns of  $G$** . Thus, the corresponding base forecasts in  $\hat{y}_h$  are not used to form the reconciled bottom-level forecasts and, moreover, are not used for all reconciled forecasts.

One way to achieve this goal is by considering an  $\ell_0$ -norm regularization. **Best-subset selection** generally performs well in high signal-to-noise (SNR) ratio regimes, while lasso performs better in low SNR regimes. We also include an additional  $\ell_2$ -norm regularization (in addition to the  $\ell_0$  penalty), which is motivated by some related works (Hastie, Tibshirani, and Tibshirani 2020; Mazumder, Radchenko, and Dedieu 2023), which suggest that when the SNR is low, additional ridge regularization can improve the prediction performance of best-subset selection.

### 1.3 Group best-subset selection with ridge regularization

The vectorization is frequently used together with the Kronecker product to express matrix multiplication as a linear transformation on matrices  $\text{vec}(ABC) = (C' \otimes A) \text{vec}(B)$ . Therefore, the QP minimization problem can be reduced to a regression problem as follows:

$$\begin{aligned} \min_G \quad & \frac{1}{2} \left( \hat{y}_h - (\hat{y}'_h \otimes S) \text{vec}(G) \right)' W_h^{-1} \left( \hat{y}_h - (\hat{y}'_h \otimes S) \text{vec}(G) \right) \\ \text{s.t.} \quad & GS = I_{n_b}. \end{aligned} \quad (2)$$

Here, we consider the following  $\ell_0\ell_2$ -**regularized regression problem** of the following form to achieve selection in hierarchical forecasting:

$$\begin{aligned} \min_G \quad & \frac{1}{2} \left( \hat{y} - (\hat{y}' \otimes S) \text{vec}(G) \right)' W^{-1} \left( \hat{y} - (\hat{y}' \otimes S) \text{vec}(G) \right) \\ & + \lambda_0 \sum_{j=1}^n \|G_{\cdot j}\|_0 + \lambda_2 \|\text{vec}(G)\|_2^2 \\ \text{s.t.} \quad & GS = I_{n_b}, \end{aligned} \quad (3)$$

where  $\lambda_0 > 0$  controls the number of non-zero columns of  $G$ , and  $\lambda_2 \geq 0$  controls the strength of the ridge regularization,  $\sum_{j=1}^n \|G_{\cdot j}\|_0$  is the number of non-zero columns of  $G$ . In a hierarchy setting, the target variable,  $\text{vec}(G)$ , in the minimization problem has a natural group structure, i.e., each column of  $G$  is a group. Thus, the  $n \times n_b$  predictors in the regularized regression problem are divided into  $n$  pre-specified, non-overlapping groups, with each group consisting of  $n_b$  predictors. Therefore, the target problem is essentially a **group best-subset selection with ridge regularization**.

### 1.4 Mixed integer program

We propose MIP formulations to solve Equation 3. We first present a **Big-M based MIP formulation** for problem Equation 3:

$$\begin{aligned}
& \min_{G, z, \tilde{e}, g^+} \frac{1}{2} \tilde{e}' W_h^{-1} \tilde{e} + \lambda_0 \sum_{j=1}^n z_j + \lambda_2 g^{+'} g^+ \\
& \text{s.t.} \quad \hat{y}_h - (\hat{y}'_h \otimes S) \text{vec}(G) = \tilde{e} \quad \dots (C1) \\
& \quad GS = I_{n_b} \Leftrightarrow (S' \otimes I_{n_b}) \text{vec}(G) = \text{vec}(I_{n_b}) \quad \dots (C2) \\
& \quad \sum_{i=1}^{n_b} g_{i+(j-1)n_b}^+ \leq \mathcal{M} z_j, \quad j \in [n] \quad \dots (C3) \\
& \quad g^+ \geq \text{vec}(G) \quad \dots (C4) \\
& \quad g^+ \geq -\text{vec}(G) \quad \dots (C5) \\
& \quad z_j \in \{0, 1\}, \quad j \in [n] \quad \dots (C6)
\end{aligned} \tag{4}$$

where,  $\mathcal{M}$  is a priori specified constant (leading to the name “Big-M”) such that some optimal solution, say  $g^{+*}$ , to Equation 4 satisfies  $\max_{j \in [n]} \sum_{i=1}^{n_b} g_{i+(j-1)n_b}^{+*} \leq \mathcal{M}$ , the binary variable  $z_j$  controls whether all the regression coefficients in group  $j$  are zero or not:  $z_j = 0$  implies that  $G_{.j} = \mathbf{0}$ , and  $z_j = 1$  implies that  $\sum_{i=1}^{n_b} g_{i+(j-1)n_b}^+ \leq \mathcal{M}$ . Such Big-M formulations are commonly used in mixed integer programming to model relations between discrete and continuous variables, and have been recently used in  $\ell_0$ -regularized regression.

This is a **Mixed Integer Quadratic Program (MIQP)** and then get solved using some efficient commercial solvers such as Gurobi, CPLEX, and MOSEK. Note that the best subset selection is an **NP-hard problem**, which is computationally intensive.

## 1.5 Hyperparameter

- $\lambda_0 = \{0, 10^{k-3}, 10^{k-2}, 10^{k-1}, 10^k, 10^{k+1}\}$ , where  $k$  is the number of digits before the decimal point for  $\frac{1}{2n_b} (\hat{y}_h - \tilde{y}_h^{\text{MinT}})' W_h^{-1} (\hat{y}_h - \tilde{y}_h^{\text{MinT}})$ . (Reason)
- $\lambda_2 = \{0, 10^{-2}, 10^{-1}, 10^0, 10^1, 10^2\}$

To avoid cross-validation, we select the best combination of  $\lambda_0$  and  $\lambda_2$  by minimizing the sum of squared reconciled forecast errors in the training set, even though fitted values are often not true one-step ahead forecasts.

## 1.6 Simulation results

### 1.6.1 Data simulation

**Structure:**

- Top: Total

- Middle: A, B
- Bottom: AA, AB, BA, BB

#### Data generation:

The bottom-level series were generated using the basic structural time series model

$$b_t = \mu_t + \gamma_t + \eta_t$$

where  $\mu_t$ ,  $\gamma_t$ , and  $\eta_t$  are the trend, seasonal, and error components, respectively,

$$\begin{aligned}\mu_t &= \mu_{t-1} + v_t + \varrho_t, & \varrho_t &\sim \mathcal{N}(\mathbf{0}, \sigma_\varrho^2 I_4), \\ v_t &= v_{t-1} + \zeta_t, & \zeta_t &\sim \mathcal{N}(\mathbf{0}, \sigma_\zeta^2 I_4), \\ \gamma_t &= -\sum_{i=1}^{s-1} \gamma_{t-i} + \omega_t, & \omega_t &\sim \mathcal{N}(\mathbf{0}, \sigma_\omega^2 \mathbf{I}_4),\end{aligned}$$

and  $\varrho_t$ ,  $\zeta_t$ , and  $\omega_t$  are errors independent of each other and over time.

#### Other details:

- $\sigma_\varrho^2 = 2$ ,  $\sigma_\zeta^2 = 0.007$ , and  $\sigma_\omega^2 = 7$ .
- $s = 4$  for quarterly data,  $n = 180$ ,  $h = 16$ .
- The initial values for  $\mu_0, v_0, \gamma_0, \gamma_1, \gamma_2$  were generated independently from a multivariate normal distribution with mean zero and covariance matrix,  $\Sigma_0 = I_4$ .
- Each component of  $\eta_t$  was generated from an ARIMA( $p, 0, q$ ) process with  $p$  and  $q$  taking values of 0 and 1 with equal probability.
- The bottom-level series were then appropriately summed to obtain the data for higher levels.
- This process was repeated 500 times.

### 1.6.2 Results

#### Scenario 0: ETS

- ETS models are used to generate base forecasts. Table 1, Table 2, and Figure 1.

Table 1: Out-of-sample average RMSE results in Scenario 0.

## 1.7 Tourism data results

### 1.7.1 Data description

Australian domestic tourism (only considering hierarchical structure)

- Monthly series from 1998 Jan to 2017 Dec.
- 240 months (20 years) for each series.
- Hierarchy: Total/State/Zone/Region, 4 levels,  $n = 111$  series in total.
- Training set: 1998 Jan-2016 Dec.
- Test set: 2017 Jan-2017 Dec.

### 1.7.2 Results

- OLS\_subset:  $\lambda_0 = 0, \lambda_2 = 0.1, \sum z = 111$
- WLSs\_subset:  $\lambda_0 = 10, \lambda_2 = 10, \sum z = 92$
- WLSv\_subset:  $\lambda_0 = 0, \lambda_2 = 100, \sum z = 111$
- MinTs\_subset:  $\lambda_0 = 0, \lambda_2 = 0, \sum z = 111$

Table 9: Out-of-sample average RMSE results in Tourism data.

## 1.8 Some issues

### NP-hard problem.

#### Setup:

- gurobipy: parameters
  - WarmStart: (1) Bottom-up, (2) All retained, (3) Relaxed problem `ifelse(z >= 0.001, 1, 0)`.
  - TimeLimit = 600s.
  - MIPGap =  $|z_P - z_D| / |z_P| = 0.01$  for large hierarchy (default value is  $10^{-4}$ ), where  $z_P$  is the primal objective bound (i.e., the incumbent objective value, which is the upper bound for minimization problems), and  $z_D$  is the dual objective bound (i.e., the lower bound for minimization problems),
  - MIPFocus = 3: when the best objective bound is moving very slowly (or not at all), this focus more on the bound.
  - Cuts = 2: aggressive cut generation.
- Bound of variables
  - should be as tight as possible to speed up computation.
  - $\tilde{e} = \hat{y} - \tilde{y} : [-|y|_{\max}, |y|_{\max}]$ .
  - $\mathcal{M}_k$  for each element in  $G$ :  $[-|G|_{\max}^{\text{bench}} - 1, |G|_{\max}^{\text{bench}} + 1]$ .
  - $\mathcal{M}$  for sum of absolute values of each column:  $[-n_b, n_b]$ .

## 2 Group lasso

### 2.1 Out-of-sample based method

#### 2.1.1 Group lasso with the unbiasedness constraint

The best-subset selection method is a NP-hard problem, which is computationally intensive.

Instead of involving an  $\ell_0$  penalty, we consider the following  $\ell_1$ -regularized regression problem of the following form to achieve selection in hierarchical forecasting:

$$\begin{aligned} \min_G \quad & \frac{1}{2} \left( \hat{y} - (\hat{y}' \otimes S) \text{vec}(G) \right)' W^{-1} \left( \hat{y} - (\hat{y}' \otimes S) \text{vec}(G) \right) \\ & + \lambda_1 \sum_{j=1}^n w_j \|G_{\cdot j}\|_2 \\ \text{s.t.} \quad & GS = I_{n_b}, \end{aligned} \tag{5}$$

where  $\lambda_1 \geq 0$  is a tuning parameter, the  $w_j$  terms account for the varying group sizes. The  $\ell_1$ -norm penalty induces sparsity in the solution. By introducing such a penalty, group lasso achieves sparse selection not of individual covariates but rather their groups. The target problem is essentially a **group lasso problem with the unbiasedness constraint**.

### 2.1.2 Second-order cone program

We propose Second-order Cone Program (SOCP) formulations to solve Equation 5.

$$\begin{aligned} \min_{G, z, \tilde{e}, g^+} \quad & \frac{1}{2} \tilde{e}' W_h^{-1} \tilde{e} + \lambda_1 \sum_{j=1}^n w_j c_j \\ \text{s.t.} \quad & \hat{y}_h - (\hat{y}_h' \otimes S) \text{vec}(G) = \tilde{e} \quad \dots (C1) \\ & c_j = \sqrt{\sum_{i=1}^{n_b} g_{i+(j-1)n_b}^2}, \quad j \in [n] \quad \dots (C2) \\ & GS = I_{n_b} \Leftrightarrow (S' \otimes I_{n_b}) \text{vec}(G) = \text{vec}(I_{n_b}) \quad \dots (C3) \end{aligned} \tag{6}$$

where constraint (C2) is a second-order cone.

### 2.1.3 Strategy & hyperparameter

#### Problem: about $w_j$ and (C3)

In a hierarchy setting, we can consider  $w_j = 1$  as each group has the same size. After experiments on simulation data and tourism data, it shows that:

- it can **hardly** shrink some columns of  $G$  to 0 when including **the unbiasedness constraint**.
- if we remove the unbiasedness constraint, it frequently gives a **top-down**  $G$  or a  $G$  with only few number of non-zero columns, and the performance is very **poor and unstable**, especially for longer horizons.

**Reason: penalty term**  $\lambda_1 \sum_{j=1}^n w_j \|G_{\cdot j}\|_2$ .

- For a given  $j$ , if  $G_{\cdot j}$  is zeroed out, then other columns of  $G$  tend to be changed, which may have larger  $\ell_2$ -norm values.
- Top level (first column) tends to have smaller  $\ell_2$ -norm when other columns are zeroed out.

**Strategy:**

- Consider a more flexible group lasso by putting different penalty weights  $w_j$  on each group, e.g.,  $w_j = 1/\|G_{\cdot j}^{\text{bench}}\|_2$ , and also include the unbiasedness constraint.
- $\lambda_1$  sequence:  $\lambda_{\max} = 10^{k+1}$ ,  $\lambda_{\min} = 10^{k-4}$  and construct a sequence of  $\lambda$  values decreasing from  $\lambda_{\max}$  to  $\lambda_{\min}$  on the log scale.
- Bound of variables
  - should be as tight as possible to speed up computation.
  - $\tilde{e} = \hat{y} - \tilde{y} : [-|y|_{\max}, |y|_{\max}]$ .
  - $\mathcal{M}_k$  for each element in  $G$ :  $[-|G|_{\max}^{\text{bench}} - 1, |G|_{\max}^{\text{bench}} + 1]$ .
  - $\mathcal{M}$  for sum of absolute values of each column:  $[-n_b, n_b]$ .

## 2.2 In-sample based method

### 2.2.1 Empirical group lasso

Here, we consider using the in-sample residuals to formulate the problem. Let  $Y$  denote  $N \times n$  matrix of historical data of all the time series in the structure, and  $\hat{Y}$  denote the matrix of in-sample 1-step-ahead forecasts of all the time series, where  $N$  is the number of historical observations for each series, and  $n$  is the number of time series in the hierarchy of interest.

Assuming that **the series in the structure are jointly weakly stationary**, the minimization problem can be given by:

$$\begin{aligned} \min_G \quad & \frac{1}{2Nn} \|Y - \hat{Y} G' S'\|_F^2 + \lambda_1 \sum_{j=1}^n w_j \|G_{\cdot j}\|_2 \\ \Downarrow \\ \min_G \quad & \frac{1}{2Nn} \|\text{vec}(Y) - (S \otimes \hat{Y}) \text{vec}(G')\|_2^2 + \lambda_1 \sum_{j=1}^n w_j \|G_{\cdot j}\|_2, \end{aligned}$$

After reformulation, it reduced to a standard group lasso problem with  $\text{vec}(Y)$  as dependent variable and  $S \otimes \hat{Y}$  as design matrix.

## 2.2.2 Strategy & hyperparameter

- Consider putting different penalty weights  $w_j$  on each group, e.g.,  $w_j = 1/\|G_j^{\text{OLS}}\|_2$ .
- Use the `gglasso` package, specify `intercept = FALSE`, `pf = w`, `lambda.factor = 1e-05`, `eps = 1e-04`, `foldid` to ensure each fold contains `t` number of observations from each variable (time series).

## 2.3 Simulation results

### 2.3.1 Scenario 0: ETS

- ETS models are used to generate base forecasts. Table 10, Table 11, and Figure 5.

Table 10: Out-of-sample average RMSE results in Scenario 0.

Figure 8: Frequency of the base forecasts being removed from reconciliation in Scenario 3.

## 2.4 Tourism data results

Use the following parameters to speed up calculations:

- NumericFocus, OptimalityTol, FeasibilityTol, BarConvTol, BarQCPCConvTol

Results:

- OLS\_Lasso:  $\lambda_1 =, \sum z =$
- WLSs\_Lasso:  $\lambda_1 =, \sum z =$
- WLSv\_Lasso:  $\lambda_1 =, \sum z =$
- MinTs\_Lasso:  $\lambda_1 =, \sum z =$
- ELasso:  $\lambda_1 =, \sum z =$

### 3 Intuitive method

### 4 Further issues

- Parallel issue: We cannot export **reticulate** `python.builtin.module` objects from one R process to another. They are designed to only work within the same R process they're created.
- HPC: gurobi license.
- Simulation: include structural break.
- Large hierarchy:
  - Candidate lambda sequence
  - Sub hierarchy + Voting
- Theoretical aspects
- Grouped time series
